Wiring

Motor can be wired for either 230 volt or 460 volt, 3 phase, 60 hz A.C. Follow jumper diagrams below.

**NOTE:**
Wiring should be done only by qualified, licensed electrician. Failure to follow standard safety precautions could lead to serious injury.

### Failure | Cause | Action
--- | --- | ---
Cable cross when standing No braking effect | Check torque unit | Two alternatives are:
1. Unit is heavily overloaded or motor has run 100%. This problem will appear within short time days to week.
2. Unit is slightly overloaded or unit is working very intensively and oil has not been changed at regular intervals. Oil with degenerate a little by little until the total volume of oil is destroyed. The crown gear will wear out. Units with very high working intensity should have there oil changed every 3 months.

Check motor
If motor is not running when cable reel is to reel in crane with trip:
Check signal from crane to motor starter.
Check logic so motor is running when crane moves to center point (against cable)
Check that motor starts again after inverting direction without stopping. (Joy-Stick full speed left to full speed right)
Check that motor starts again after inverting direction with a stop in between (brakes applied)

Check motor
Check that motor is not always on. Motor should be on only when reeling in. Check motor delay off timer. If delay is too long or timer is not working gearbox will overheat. Correct timer setting is approx. 5 sec.

Reel pulling too hard | Lower torque | Set torque level
--- | --- | ---

Crate trips when reeling in | Slack cable switch in cable guide | Check that signal is correct and that signal is not too early. A movement of the pendulum must be accepted, signal should come slightly before pendulum reaches its vertical position.

| Torque unit                               | Disassemble and check friction plates. |                                                                          |
| Excessive cable length and/or weight      | Check design data              |                                                                          |
| Torque unit friction plates worn out      | Replace worn out parts.        |                                                                          |

- The cable reel motor must be energized during reeling in of the cable (machine travelling toward the feed point). During paying out (machine travelling away from feed point) and at stand still, the reel motor must not be energized. When paying out, the release of the cable is obtained through the controlled slippage of the hydrodynamic clutch inside the torque unit.

- The timer D (delayed opening 2-3 sec.) delays the disconnection of the cable reel motor with respect to the crane advance motors in order to ensure proper cable tension.

---

WARNING! Emergency circuit contacts cannot be delayed for any reason.

---

![Diagram of emergency circuit](image-url)
TORQUE OUTPUT REGULATION

1. Unscrew torque regulating key (see drawing).
2. Turn key upside down and replace it into torque unit.
3. Turn drum slowly until key enters completely in the hole into locked position.
4. Turn drum clockwise to increase torque; turn drum counter-clockwise to decrease torque. (cable reel seen from the drum side).

Adjust torque by turning the drum a quarter to half a turn at a time. The torque must be sufficient to recover the cable at full drum but should not exert too much pull on the cable when drum is empty.

On completion, remove regulating key and replace it in the correct way round.

WARNING!
The regulation has no safety limitation. Over torque settings may damage the worm screw and crown gear and cause internal vibrations.

Driving a crane with torque setting key locked (inserted position 2) will damage the gearbox.

NOTE! At delivery the torque output is pre-set at 75% (for units 10.0-20.0-40.0) of the nominal torque value of the unit.

It might therefore be necessary to adjust the output on site at start-up accordingly to the specific torque requirement of each application.

For the 120.0 unit the torque output is pre-set at the theoretical torque value for the application. Field adjustment is always required.

Motor running No torque | Torque not set in torque unit | Set torque see torque setting instructions |

When setting torque only turn drum 1/4 of a turn at a time and check result. Then, readjust if necessary.

Maximum torque is needed when drum is nearly full (horizontal travel application). Check functions in this area.

Do not set torque higher than necessary.
Electric motor (if any)
- Keep the motor surface clean, in order to ensure a proper cooling. The ball bearings do not need any maintenance, since they are of the sealed type, life-lubricated.

Hydraulic motor (if any)
- Check fittings.

Drum
- Check regularly the gap between spokes: at the inner ring is cable diameter + 10% (max. 4mm) and at the outer diameter corresponds to cable diameter + 2.3 mm.

**EVERY TWELVE MONTHS:**

General
- Carry out all the operations described in the previous points.

Torque unit
- Change oil in the torque unit. The oil to be used for ambient temperatures between -15° and +38°C is Esso GX 85W-140. For ambient temperatures between -24°C and +38°C use oil Esso GX 80W-90.
- For higher or lower temperatures please contact the manufacturer or one of his representatives.
- Note! When the reel is used for severe applications (i.e. vertical recovery or continuous operation) the oil should be changed about every 500 hours of work.
- Recheck the torque. If torque adjustment is needed decrease or increase the torque setting for a lower or higher torque requested by the single application.
- Limit switch (if any): check cam positions and that switches are operating.
- Heaters (if any): check that they are operating.

**HOW TORQUE UNIT WORKS**

Gleason series MRH reels feature torque units which work on a patented self braking hydrodynamic clutch system.

The Functions of the torque unit are:
- To provide a constant torque on the drum shaft.
- To gear the drum rotating speed to the reeling diameter of the cable.
- To brake the drum when stationary.
- To allow a controlled unreeling of the cable.
- To regulate the torque output according to the requirements of each application.

The torque unit is powered by a motor rotating at a constant speed. Normally a conventional electric squirrel cage motor is used but the unit can also be powered by an air or a hydraulic motor.

The torque of the driving motor is transmitted to the drum shaft through a hydrodynamic clutch which is combined with a worm gear reduction. The output torque is only minimally affected by the rotating speed of the input and output shafts. The output torque can be set from zero to maximum torque through a spring arrangement in the clutch.

![Section View of Torque Unit](image-url)
Following is a brief description of the torque unit components:

(Please refer to drawing on page 5)

The bronze crown gear (item 3) has specially machined surfaces on both sides. Freely mounted on the drum shaft (item 1), the crown gear is linked to the motor via a worm gear (item 2).

There are two friction plates (items 4 & 5), one on each side of the crown gear. They are made of steel and are fixed to the drum shaft with keys. The friction plates are also specially machined so that an oil film is created between the plates and the crown gear. The oil film allows slippage as torque is transferred from the crown gear to the friction plates. Pulling force on the cable remains constant, even with the motor running at a constant speed, and is fully adjustable.

The special machining on the clutch surfaces assures that they remain lubricated, even when clutch is not moving, eliminating the normally occurring “stick-slip” effect. Variation between dynamic and static friction remains within 3-10% depending on size of the torque unit.

Since the worm gear is irreversible, the clutch also acts as a brake when the motor is off. This provides two major advantages:

A) Electro-magnetic brake, required on conventional cable reels, is not needed.

B) Braking torque is the same as reeling torque, avoiding uneven pulling force on the cable when the motor is switched on and off.

The torque unit has an adjustable spring assembly to vary the pressure on the clutch and obtain the required output. The spring assembly consists of the rear friction plate (item 5), compression springs (item 6), the spring holder plate (item 7) and the torque regulating nut (item 8).

The springs are placed between the rear friction plate and the spring holder which is fixed onto the drum shaft with a key, allowing it to slide along the shaft. The torque regulating nut is screwed onto the drum shaft and pushes against the spring holder plate through a series of steel ball bearings.

Torque can be regulated by placing the torque regulating key (item 10) upside down into the torque unit, preventing the regulating nut from rotating. With the regulating nut held in position, the drum can be turned manually or with the help of the cable reel motor to increase or decrease the pressure on the spring assembly thereby increasing or decreasing the torque output of the clutch. Refer to “TORQUE OUTPUT REGULATION”, page 4, for details.

MAINTENANCE INSTRUCTIONS

Gleason cable and hose reels are designed so that maintenance is reduced to a minimum. However, in order to guarantee a correct and continuous function of the reel, it is necessary to follow a few simple rules, hereafter described.

AFTER FIRST OPERATING WEEK:

Drum
- Verify the tightening of all bolts and nuts including the ones fixing the torque unit onto its support, the collector, the drum and the motor to the torque unit.
- In case that the drum is of a monospiral type check that the spacing between the wheels at the inner ring is cable diameter + 10% (max. 4 mm) and at the outer diameter corresponds to cable diameter + 2.3 mm.

Collector (if any)
- Verify tightening of all electrical connections and check ring - brush alignment. All carbon brushes must be in the grooves of the rings.
- Note! Always switch current off before removing collector cover.

AT REGULAR INTERVALS (TWO MONTHS):

The frequency of those regular checks will also depend on the severity of the environment in which the reel is working and on the duty cycle intensity.

Collector (if any)
- Verify tightening of all electrical connections and check ring - brush alignment. All carbon brushes must be in the grooves of the rings.
- Note! Always switch current off before removing collector cover.

- If necessary clean collector inside noting the following:
  a) Never use water when cleaning. Use vacuum cleaner, brush or lint-free cloth.
  b) Slip rings must be dry, clean and free from oil or other covering stains.
  c) If any part is found to be damaged it must be replaced as soon as possible with a new original spare part.
  d) After cleaning the rings remove the collector housing ensuring that the drainage holes are downwards. Also make sure the rubber gasket is in place with its joint downwards as well. This will ensure a good sealing.

Rotary joint (if any)
- Change the gasket only if there are some dribbles. The ball bearings do not need any maintenance, since they normally are life-lubricated; on the contrary there will be special instructions about the lubrication.

Torque unit
- Check oil level through the level gauge, and, if necessary, top it up with the oil type specified further on.

- With the aid of a dynamometer check that the output torque has not changed since start-up due to the setting of mechanical components during run-in. The torque should be set so that the cable is pulled up evenly, without slackening or excessive tension.
Following is a brief description of the torque unit components:

(Please refer to drawing on page 5)

The bronze crown gear (item 3) has specially machined surfaces on both sides. Freely mounted on the drum shaft (item 1), the crown gear is linked to the motor via a worm gear (item 2).

There are two friction plates (items 4 & 5), one on each side of the crown gear. They are made of steel and are fixed to the drum shaft with keys. The friction plates are also specially machined so that an oil film is created between the plates and the crown gear. The oil film allows slippage as torque is transferred from the crown gear to the friction plates. Pulling force on the cable remains constant, even with the motor running at a constant speed, and is fully adjustable.

The special machining on the clutch surfaces assures that they remain lubricated, even when clutch is not moving, eliminating the normally occurring “stick-slip” effect. Variation between dynamic and static friction remains within 3-10% depending on size of the torque unit.

Since the worm gear is irreversible, the clutch also acts as a brake when the motor is off. This provides two major advantages:

A) Electro-magnetic brake, required on conventional cable reels, is not needed.

B) Braking torque is the same as reeling torque, avoiding uneven pulling force on the cable when the motor is switched on and off.

The torque unit has an adjustable spring assembly to vary the pressure on the clutch and obtain the required output. The spring assembly consists of the rear friction plate (item 5), compression springs (item 6), the spring holder plate (item 7) and the torque regulating nut (item 8).

The springs are placed between the rear friction plate and the spring holder which is fixed onto the drum shaft with a key, allowing it to slide along the shaft. The torque regulating nut is screwed onto the drum shaft and pushes against the spring holder plate through a series of steel ball bearings.

Torque can be regulated by placing the torque regulating key (item 10) upside down into the torque unit, preventing the regulating nut from rotating. With the regulating nut held in position, the drum can be turned manually or with the help of the cable reel motor to increase or decrease the pressure on the spring assembly thereby increasing or decreasing the torque output of the clutch. Refer to “TORQUE OUTPUT REGULATION”, page 4, for details.

HOW TORQUE UNIT WORKS

Gleason series MRH reels feature torque units which work on a patented self braking hydro-

dynamic clutch system.

The Functions of the torque unit are:
- To provide a constant torque on the drum shaft.
- To gear the drum rotating speed to the reeling diameter of the cable.
- To brake the drum when stationary.
- To allow a controlled unreeling of the cable.
- To regulate the torque output according to the requirements of each application.

The torque unit is powered by a motor rotating at a constant speed. Normally a conventional
electric squirrel cage motor is used but the unit can also be powered by an air or a hydraulic
motor.

The torque of the driving motor is transmitted to the drum shaft through a hydrodynamic
clutch which is combined with a worm gear reduction. The output torque is only minimally
affected by the rotating speed of the input and output shafts. The output torque can be set
from zero to maximum torque through a spring arrangement in the clutch.
TORQUE OUTPUT REGULATION

1. Unscrew torque regulating key (see drawing).
2. Turn key upside down and replace it into torque unit.
3. Turn drum slowly until key enters completely in the hole into locked position.
4. Turn drum clockwise to increase torque; turn drum counter-clockwise to decrease torque. (cable reel seen from the drum side).

Adjust torque by turning the drum a quarter to half a turn at a time. The torque must be sufficient to recover the cable at full drum but should not exert too much pull on the cable when drum is empty.

On completion, remove regulating key and replace it the correct way round.

WARNING!
The regulation has no safety limitation. Over torque settings may damage the worm screw and crown gear and cause internal vibrations.

Driving a crane with torque setting key locked (inserted position 2) will damage the gearbox.

NOTE! At delivery the torque output is pre-set at 75% (for units 10.0-20.0-40.0) of the nominal torque value of the unit.

It might therefore be necessary to adjust the output on site at start-up accordingly to the specific torque requirement of each application.

For the 120.0 unit the torque output is pre-set at the theoretical torque value for the application. Field adjustment is always required.

| Oil damaged                                  | Change oil                         | When oil gets burnt or damaged the result can be a loss in output torque.  
Change only to specified oil type           |
| Torque unit                                  | Disassemble and check friction plates. |                                                                          |
| Excessive cable length and/or weight         | Check design data                  |                                                                          |
| Torque unit friction plates worn out         | Replace worn out parts.            |                                                                          |
| Reel working vibrations or sounds when reeling out | Check oil                        | Change oil  
If oil is not correct type or there is water in the oil vibrations can easily happen.  
Type should be ESSO GX 85W140 or ESSO GX 80W90 for low ambient temperature applications.  
No similar oils from other manufacturers are recommended.  
If unit is set to a very high torque this phenomena can occur during running in when the crane is moving slowly (reel rotating)  
Consult with Greasen for a possible solution. |
| Cable drops when standing No braking effect  | Check torque unit                  | This will normally happen if unit has been overheated and the oil has been burnt.  
Teeth on crown gear not existing anymore. |

- The cable reel motor must be energized during reeling in of the cable (machine travelling toward the food point). During paying out (machine travelling away from food point) and at stand still, the reel motor must not be energized. When paying out, the release of the cable is obtained through the controlled slippage of the hydrodynamic clutch inside the torque unit.

- The timer D (delayed opening 2-3 sec.) delays the disconnection of the cable reel motor with respect to the crane advance motors in order to ensure proper cable tension.

- WARNING! Emergency circuit contacts cannot be delayed for any reason.
Wiring

Motor can be wired for either 230 volt or 460 volt, 3 phase, 60 hz A.C. Follow jumper diagrams below.

NOTE:
Wiring should be done only by qualified, licensed electrician. Failure to follow standard safety precautions could lead to serious injury.

V2 U2 W2 BLK GRN BLU BRN YLW RED

230 volts

<tbody>
<tr>
<td>Cable cross when standing No braking effect</td>
<td>Check torque unit</td>
<td>Two alternatives are: 1. Unit is heavily overloaded or motor has run 100%. This problem will appear within short time days to week. 2. Unit is slightly overloaded or unit is working very intensively and oil has not been changed at regular intervals. Oil with degenerate a little by little until the total volume of oil is destroyed the crown gear will wear out. Units with vary high working intensity should have there oil changed every 3 months.</td>
</tr>
<tr>
<td>Check motor</td>
<td>If motor is not running when cable reel is to reel in crane with trip. Check signal from crane to motor starter.</td>
